- 1. [Probability] Assume that the probability of obtaining heads when tossing a coin is λ .
 - a. What is the probability of obtaining the first head at the (k+1)-th toss?
 - b. What is the expected number of tosses needed to get the first head?

Solution:

a.

 $\Pr(k \text{ tails in the first } k \text{ tosses, then 1 head}) = (1 - \lambda)^k \lambda$

b. Let X be the number of the tosses required to get the first head and let S = E[X]. There are many ways to solve this problem.

Solution (1): Using the definition of expectation. By definition,

$$S = E[X] = \sum_{i=1}^{\infty} i \times \lambda \times (1 - \lambda)^{i-1} = \lambda \sum_{i=1}^{\infty} i \times (1 - \lambda)^{i-1}.$$
 (1)

Let

$$f(\lambda) = \sum_{i=1}^{\infty} (1 - \lambda)^{i} = \frac{1 - \lambda}{\lambda}.$$

Then, we have

$$\sum_{i=1}^{\infty} i \times (1-\lambda)^{i-1} = -f'(\lambda) = \frac{1}{\lambda^2}.$$
 (2)

With substitution of Eq. (2) into Eq. (1), we find the expectation of number of tosses is $\frac{1}{\lambda}$.

Solution (2): Using properties of expectation.

Given that tosses are independent, and expectation is additive:

$$S = \lambda \times 1 + (1 - \lambda) \times (S + 1)$$

Solving for S gives $S = \frac{1}{\lambda}$.

Solution (3): Using moment generating function.

The moment generating function $\phi(t)$ of X is

$$\phi(t) = E[e^{tX}] = \sum_{x=1}^{\infty} e^{tx} P(X = x) = \sum_{x=1}^{\infty} e^{tx} \lambda \times (1 - \lambda)^{x-1} = \frac{\lambda e^t}{1 - e^t (1 - \lambda)}.$$

Then,

$$E[X] = \frac{d}{dt}E[e^{tX}] \mid_{t=0} = \frac{d}{dt}\phi(t) \mid_{t=0} = \frac{\lambda e^t}{(1 - e^t(1 - \lambda))^2} \mid_{t=0} = \frac{1}{\lambda}.$$

- 2. [Probability] Assume X is a random variable.
 - a. We define the variance of X as: $Var(X) = E[(X E[X])^2]$. Prove that $Var(X) = E[X^2] E[X]^2$.
 - b. If E[X] = 0 and $E[X^2] = 1$, what is the variance of X? If Y = a + bX, what is the variance of Y?

Solution:

a. Directly from the definition of variance:

$$E[(X - E[X])^{2}] = E[X^{2} - 2XE[X] + E[X]^{2}] = E[X^{2}] - 2E[XE[X]] + E[X]^{2}$$
$$= E[X^{2}] - 2E[X]^{2} + E[X]^{2} = E[X^{2}] - E[X]^{2}$$
(3)

where the second equality makes use of the additivity of expectations and the third makes use of the fact that E[X] is a constant.

b. Substituting the values for E[X] and $E[X^2]$ in Eq. 3, we get

$$Var(X) = E[X^2] - E[X]^2 = 1$$

If Y = a + bX,

$$\begin{split} E[Y^2] &= E[(a+bX)^2] = E[a^2 + 2abX + b^2X^2] \\ &= a^2 + 2abE[X] + b^2E[X^2] = a^2 + b^2 \\ E[Y] &= E[a+bX] = a + bE[X] = a \\ Var(Y) &= E[Y^2] - E[Y]^2 = a^2 + b^2 - a^2 = b^2 \end{split}$$

- [Probability] John is a great fortune teller. Assume that we know three facts: 1) If John tells you that a lottery ticket will win, it will win with probability 0.99. 2) If John tells you that a lottery ticket will not win, it will not win with probability 0.99999.
 With probability 10⁻⁵, John predicts that a ticket as a winning ticket. This also means that with probability 1 10⁻⁵, John predicts that a ticket will not win.
 - a. Given a ticket, what is the probability that it wins?
 - b. What is the probability that John correctly predicts a winning ticket?

Solution: Let T be the event "John predicts that a given ticket is a winning ticket". Let $\neg T$ be the event "John predicts that a given ticket is not a winning ticket". Similarly, let W be the event that the given ticket wins and $\neg W$ be the event that the given ticket does not win. Then:

a. Given a ticket, the probability that it wins is:

$$P(W) = P(W,T) + P(W,\neg T) = P(W \mid T)P(T) + P(W \mid \neg T)P(\neg T)$$

= 0.99 × 10⁻⁵ + (1 - 0.99999) × (1 - 10⁻⁵)
\approx 1.99 × 10⁻⁵

b. The probability that John correctly predicts a winning ticket is:

$$P(T|W) = \frac{P(T,W)}{P(W)} = \frac{P(W \mid T)P(T)}{P(W)}$$

$$= \frac{0.99 \times 10^{-5}}{0.99 \times 10^{-5} + (1 - 0.99999) \times (1 - 10^{-5})}$$

$$\approx 0.497$$

- 4. [Calculus] Let $f(x, y) = 3x^2 + y^2 xy 11x$
 - a. Find $\frac{\partial f}{\partial x}$, the partial derivative of f with respect to x. Find $\frac{\partial f}{\partial y}$.
 - b. Find $(x,y) \in \mathbb{R}^2$ that minimizes f.

Solution: This question serves as a review of multivariate calculus.

a.
$$\frac{\partial f}{\partial x} = 6x - y - 11$$
 $\frac{\partial f}{\partial y} = 2y - x$

b. Recall from basic calculus that a function attains its maxima and minima at points where the derivative is zero. Setting the derivative from (a.) to zero, we see that f is maximized or minimized at (x, y) = (2, 1).

One approach to show that this point is a minimizer is to consider the matrix of second derivatives, the Hessian, and show that it is <u>positive definite</u>. In our case, the Hessian is

$$H_f = \begin{bmatrix} \frac{\partial^2 f}{\partial x^2} & \frac{\partial^2 f}{\partial x \partial y} \\ \frac{\partial^2 f}{\partial x \partial y} & \frac{\partial^2 f}{\partial y^2} \end{bmatrix} = \begin{bmatrix} 6 & -1 \\ -1 & 2 \end{bmatrix}$$

This matrix is positive definite for all (x, y) because the principal minors are positive. Another way to check if H_f is positive definite is to verify if $z^T H_f z$ is positive for every non-zero column vector $z = [z_1 \ z_2]^T$:

$$z^{T}H_{f}z = 6z_{1}^{2} - 2z_{1}z_{2} + 2z_{2}^{2} = 5z_{1}^{2} + z_{2}^{2} + (z_{1} - z_{2})^{2} > 0$$

- 5. [Linear Algebra] Assume that $w \in \mathbb{R}^n$ and b is a scalar. A hyper-plane in \mathbb{R}^n is the set, $\{x : x \in \mathbb{R}^n, w^T x + b = 0\}$.
 - a. For n=2 and 3, find two example hyper-planes (say, for n=2, $w^T=\begin{bmatrix} 1 & 1 \end{bmatrix}$ and b=2 and for n=3, $w^T=\begin{bmatrix} 1 & 1 & 1 \end{bmatrix}$ and b=3) and draw them on a paper.
 - b. The distance between a point $x_0 \in \mathbb{R}^n$ and the hyperplane $w^T x + b = 0$ can be described as the solution of the following optimization problem:

$$\min_{x} ||x_0 - x||^2$$

s.t. $w^T x + b = 0$

However, it turns out that the distance between x_0 and $w^T x + b = 0$ has an analytic solution. Derive the solution. (*Hint: you may be familiar with another way of deriving this distance; try your way too*)

c. Assume that we have two hyper-planes, $w^T x + b_1 = 0$ and $w^T x + b_2 = 0$. What is the distance between these two hyperplanes?

Solution: This problem will also appear in Hw1. We will release the solution later.

6. [Linear Algebra] One way to define a <u>convex</u> function is as follows. A function f(x) is convex if

$$f(\lambda x + (1 - \lambda)y) \le \lambda f(x) + (1 - \lambda)f(y)$$

for all x, y and $0 < \lambda < 1$.

- a. Prove that $f(x) = x^2$ is a convex function. (Prove by applying the definition.)
- b. A *n*-by-*n* matrix *A* is a <u>positive semi-definite</u> matrix if $x^T A x \ge 0$, for any $x \in \mathbb{R}^n$ s.t $x \ne 0$.

Prove that the function $f(x) = x^T A x$ is convex if A is a positive semi-definite matrix. Note that x is a vector here. (Hint: the solution is somewhat similar to the solution of part (a.))

Solution:

a. We use the definition of convex function:

$$f(\lambda x + (1 - \lambda)y) - \lambda f(x) - (1 - \lambda)f(y)$$

$$= (\lambda x + (1 - \lambda)y)^{2} - \lambda x^{2} - (1 - \lambda)y^{2}$$

$$= \lambda^{2}x^{2} + (1 - \lambda)^{2}y^{2} + 2\lambda(1 - \lambda)xy - \lambda x^{2} - (1 - \lambda)y^{2}$$

$$= (\lambda^{2} - \lambda)x^{2} + ((1 - \lambda)^{2} - (1 - \lambda))y^{2} + 2\lambda(1 - \lambda)xy$$

$$= (\lambda - 1)\lambda(x^{2} + y^{2} - 2xy)$$

$$= (\lambda - 1)\lambda(x - y)^{2} \le 0$$

Note that the last inequality comes from the fact $0 < \lambda < 1$.

b. As in (a.), using the definition:

$$f(\lambda x + (1 - \lambda)y) - \lambda f(x) - (1 - \lambda)f(y)$$

$$= (\lambda x + (1 - \lambda)y)^{T} A(\lambda x + (1 - \lambda)y) - \lambda x^{T} Ax - (1 - \lambda)y^{T} Ay$$

$$= \lambda^{2} x^{T} Ax + (1 - \lambda)^{2} y^{T} Ay + \lambda (1 - \lambda)x^{T} Ay + \lambda (1 - \lambda)y^{T} Ax - \lambda x^{T} Ax - (1 - \lambda)y^{T} Ay$$

$$= (\lambda^{2} - \lambda)x^{T} Ax + ((1 - \lambda)^{2} - (1 - \lambda))y^{T} Ay + \lambda (1 - \lambda)x^{T} Ay + \lambda (1 - \lambda)y^{T} Ax$$

$$= (\lambda - 1)\lambda(x^{T} Ax + y^{T} Ay - x^{T} Ay - y^{T} Ax)$$

$$= (\lambda - 1)\lambda(x - y)^{T} A(x - y) \le 0$$

The last inequality holds because A is positive semi-definite.

7. [CNF and DNF] Consider the following Boolean function written in a conjunctive normal form

$$(x_1 \vee x_2) \wedge (x_3 \vee x_4) \wedge \dots (x_{15} \vee x_{16})$$

If no new variable is introduced, how many clauses do you need to write down the same function in disjunctive normal form ?

Solution: Each clause in the final disjunctive normal form (DNF) should be of the form $x_{i_1} \wedge x_{i_2} \wedge \ldots \wedge x_{i_8}$, where i_1 can be 1 or 2, i_2 can be 3 or 4, and so on. Therefore, 2^8 clauses are needed to write out the final DNF.
